How is this agent running?

truthops

Analysis

Investigating Workflow Performance

I'm currently analyzing the execution of the "truthops" workflow within the specified date range. My focus is on understanding its operational dynamics and performance metrics during that period.

Fetched traces from 2026-09-28 to 2026-10-12

Analyzing Agent Performance

I'm currently processing your request to understand agent activity. Deep mode is engaged, so I'm initiating a background task to thoroughly examine workflow traces and performance metrics within your specified parameters. I'll provide a comprehensive update once this analysis is complete.

Processed delegate task

Delegating Task Execution

I've successfully queued the background task. Its execution is now delegated, and you can expect the results to be delivered automatically. I'll provide a high-level overview of what we anticipate.

Initial Observations (Recent Samples)

While the background analyzer compiles the complete dataset, here is a quick look at the execution patterns observed in the most recent traces:

Based on the background analysis of the `truthops` workflow agent for the period **2026-09-28 to 2026-10-12** , here is the synthesized overview of how this agent is running:

1. Active Traces & Execution Flow (Observed Samples)

A sample of recent traces shows the `truthops` workflow executing several distinct steps:

- **Search & Scrape Steps:** Spans like `evidence.alexandria_search` and `evidence.alexandria_scrape` indicate the agent actively searches and retrieves evidence.
- **Evaluation & Review Steps:** Spans like `evidence.evaluate` and `contrarian.review` process the retrieved information.
- **Planning & Response Steps:** Spans like `response.build_plan` compile the final outputs.

2. Active Detections & Monitors

The system has **15 active detections** configured for this environment, specifically targeting key execution behaviors:

- **Slow Chain Execution Monitor** (ID: `d803b501-34f4-4b96-a4f3-f77096e9ee5a`): Triggered on high-latency steps (e.g., observed on `evidence.alexandria_scrape` spans with latencies of ~1.9s to ~2.2s).
- **Contrarian Viewpoint Detector** (ID: `9ec67f0a-2647-453f-bb26-7b04f2cc758e`): Triggered on spans performing contrarian analysis (e.g., `contrarian.review`).
- **TruthOps Execution Monitor** (ID: `c5761681-47d4-44a9-afae-3ba7d6dbcb6d`): Specifically monitors the execution of this workflow.
- **Alexandria Scrape Usage Monitor** (ID: `dc4a468c-b46a-48b2-bfd9-11812e77d1f1`): Tracks usage patterns of the Alexandria scrape utility.

3. Failures & Missing Operational Metrics (Limitations)

Due to failures in executing analytical database queries (`run_analytics_query` failed during background execution), we face the following limitations and uncertainties:

- **Total Volume & Error Rates:** The exact total number of runs during this window, as well as the overall workflow-level error rate, could not be calculated.
- **Latency Distribution:** Exact latency quantiles (p50, p90, p99) for the overall workflow are unverified.
- **Detection Frequency:** The exact occurrence rates for how often the *Slow Chain Execution Monitor* or *Contrarian Viewpoint Detector* triggered across the entire population remain unquantified.

Ask anything....
